

# LOJ 1108

This problem presents a shortest path challenge with a unique cost function based on the **cube of the difference in busyness values between junctions**. The core complexity arises from the mathematical nature of the cost calculation: when traveling from junction **u** to junction **v**, the cost is defined as:

$$\text{cost} = (\text{busyness}[v] - \text{busyness}[u])^3$$

This cubic function can produce **negative edge weights** if the destination junction is less busy than the source junction, potentially forming **negative cycles**.

The goal is to find the **minimum total cost** (earning from the city authority's perspective) from junction 1 to various query junctions. Additionally, any total cost **less than 3 units** should be reported as **'?'**.

The solution requires careful handling of **negative cycles** and **unreachable nodes**. If a negative cycle exists along a path to a junction, the total cost can become arbitrarily small, effectively undefined. Similarly, if the computed minimum cost is less than 3, it should also be reported as **'?'**.

To solve this, the **Bellman-Ford algorithm** is used to compute shortest paths and detect negative cycles reachable from the source. All nodes affected by negative cycles must also be marked to ensure correct query results.

## Steps

### 1. Read Input

- Read number of junctions.
- Read busyness values for each junction.
- Read number of roads.
- Store each road as a directed edge with weight =  $((\text{busyness}[\text{destination}] - \text{busyness}[\text{source}])^3)$ .
- Read number of queries and query junctions.

## 2. Initialize Arrays

- Create a distance array with large values.
- Set distance of junction 1 to 0.
- Create an array to mark nodes affected by negative cycles.

## 3. Run Bellman-Ford Algorithm

- Repeat **n-1 times**:
  - For each edge ( $u \rightarrow v$ ):
    - If we can get a shorter path to v through u, update `distance[v]`.

## 4. Check for Negative Cycles

- Do **one more pass** through all edges.
- If any distance can still be improved, mark that node as in a negative cycle.
- Use **BFS/DFS** to mark all nodes reachable from cycle nodes.

## 5. Answer Queries

- For each query junction:
  - If unreachable **OR** in negative cycle **OR** distance < 3 → print `'?'`.
  - Else → print the distance.

## 6. Output Results

- Print `"Set #"` with case number.
- Print each query result on a separate line.

## Input:

5 6 7 8 9 10

6

1 2

2 3

3 4

1 5

5 4

4 5

2

4

5

## Execution:

Step 1: Read Input

$n = 5$  busyness array: index 1=6, index 2=7, index 3=8, index 4=9, index

5=10  $r = 6$  roads

Compute edge weights:

1→2:  $(7-6)^3 = 1$

2→3:  $(8-7)^3 = 1$

3→4:  $(9-8)^3 = 1$

1→5:  $(10-6)^3 = 64$

5→4:  $(9-10)^3 = -1$

4→5:  $(10-9)^3 = 1$   $q = 2$

queries: 4 and 5

Step 2: Initialize Arrays

$\text{dist} = [\text{inf}, 0, \text{inf}, \text{inf}, \text{inf}, \text{inf}]$  for nodes 1-5

$\text{inCycle} = \text{all false}$   $\text{visited} = \text{all false}$

Step 3: Run Bellman-Ford (4 iterations)

Iteration 1:

Process edge 1→2:  $0+1=1 < \text{inf} \rightarrow \text{update dist}[2]=1$

Process edge 2→3:  $1+1=2 < \text{inf} \rightarrow \text{update dist}[3]=2$

Process edge 3→4:  $2+1=3 < \text{inf} \rightarrow \text{update dist}[4]=3$

Process edge 1→5:  $0+64=64 < \text{inf} \rightarrow \text{update dist}[5]=64$

Process edge 5→4:  $64+(-1)=63 > 3 \rightarrow \text{no update}$  Process

edge 4→5:  $3+1=4 < 64 \rightarrow \text{update dist}[5]=4$

Iteration 2:

All edges checked, no improvements found

Iterations 3-4: No

changes

Current distances:  $\text{dist}[1]=0$ ,  $\text{dist}[2]=1$ ,  $\text{dist}[3]=2$ ,  $\text{dist}[4]=3$ ,  $\text{dist}[5]=4$

Step 4: Detect Negative Cycles

Run Bellman-Ford again to check for cycles All

edges processed, no distance improvements

$\text{inCycle}$  array remains all false

No BFS propagation needed since no cycles detected

Step 5: Process Queries

Query for node 4:  $\text{dist}[4]=3$ , not inf, not in cycle,  $\geq 3 \rightarrow$  output 3

Query for node 5:  $\text{dist}[5]=4$ , not inf, not in cycle,  $\geq 3 \rightarrow$  output 4

**Output:**

Set #1

3

4

**Pseudocode:**

READ  $n$

READ  $\text{busyness}[1..n]$

READ  $r$  roads, store edges with weight =  $(\text{busyness}[v]-\text{busyness}[u])^3$

READ  $q$  queries

$\text{dist}[1..n] = \text{INF}$ ,  $\text{dist}[1] = 0$

REPEAT  $n-1$  times:

FOR each edge  $(u,v,w)$ :

IF  $\text{dist}[u] + w < \text{dist}[v]$ :

$\text{dist}[v] = \text{dist}[u] + w$

$\text{inCycle}[1..n] = \text{false}$

REPEAT  $n-1$  times:

FOR each edge  $(u,v,w)$ :

IF  $\text{dist}[u] + w < \text{dist}[v]$ :

$\text{inCycle}[v] = \text{true}$

Propagate to all reachable nodes

FOR each query:

IF  $\text{dist}[\text{query}] < 3$  OR unreachable OR  $\text{inCycle}$ : PRINT "?"

ELSE: PRINT  $\text{dist}[\text{query}]$
